HYPOTHESIS TESTING
TESTING THE DISTRIBUTION SHAPE OF CONTINUOUS DATA

Sorana D. Bolboacă
OBJECTIVES

- Testing hypothesis: General Approach
- Data follows a normal distribution?
  - Could be applied on any type of distribution (Binomial, Poisson, etc.)
- Two distributions has the same shape?
  - Could not answer to the question: “Which is the shape of the distribution?”
  - Tell us if the shapes of distributions of two samples are the same or are different
TESTING HYPOTHESIS

- Understand the principles of hypothesis-testing
- To be able to correctly interpret P values
- To know the steps needed in application of a statistical test
“Medical students may not like statistics, but as doctors they will.”

“Medical students may not like statistics, but as good doctors they will have to understand statistics.”

John Chen, 2004, Advice to GCRC & Surgery Fellows and Residents
DEFINITIONS

- **Statistical hypothesis test** = a method of making statistical decisions using experimental data.
- A result is called **statistically significant** if it is unlikely to have occurred by chance.
- Statistical hypothesis = an assumption about a population parameter. This assumption may or may not be true.
- Clinical hypothesis = a single explanatory idea that helps to structure data about a given client in a way that leads to better understanding, decision-making, and treatment choice.

DEFINITIONS

Clinical hypothesis:
- A proposition, or set of propositions, set forth as an explanation for the occurrence of some specified group of phenomena, either asserted merely as a provisional conjecture to guide investigation (working hypothesis) or accepted as highly probable in the light of established facts.
- A tentative explanation for an observation, phenomenon, or scientific problem that can be tested by further investigation.
- Something taken to be true for the purpose of argument or investigation; an assumption.
HYPOTHESIS TESTING

- Hypothesis testing is a form of inferential statistics used to determine the probability (or likelihood) that a conclusion based on analysis of data from a sample is true.
- We use hypothesis testing to make comparisons between:
  - One sample and a population
  - Between 2 or more samples
- A statistical hypothesis test produces a p-value, or the probability of obtaining the results (or more extreme results) from tests of samples, if the results really were not true in the population.
**Statistical Test Frequently Used in Medicine**

- **Parametric tests** (quantitative normal distributed data):
  - T-test for dependent or independent samples (2 groups)
  - ANOVA (2 or more groups)

- **Non-parametric tests** (qualitative data – nominal or ordinal):
  - Chi-Square test
  - Fisher’s exact test

- **Test for associations** (quantitative & qualitative data):
  - Correlation (Pearson & Spearman) & Regression (Linear & Logistic)
HYPOTHESIS TESTING

- In all hypothesis testing, the numerical result from the statistical test is compared to a probability distribution to determine the probability of obtaining the result if the result is not true in the population.
FROM PROBABILITY TO HYPOTHESIS TESTING

Sampling

Probability

Descriptive statistics

Inference (Inferential statistics)

Population Parameters ($\mu$, $\sigma$)

Sample Statistics ($m$, $s$)
FROM PROBABILITY TO HYPOTHESIS TESTING

What we Learned from Probability

1) The mean of a sample can be treated as a random variable.

2) By the central limit theorem, sample means will have a normal distribution (for n > 30) with $\mu_{\bar{X}} = \mu$ and $\sigma_{\bar{X}} = \frac{\sigma}{\sqrt{n}}$

3) Because of this, we can find the probability that a given population might randomly produce a particular range of sample means.

$$P(\bar{X} > \text{something}) = P(Z > \text{something}) = \text{Use standard table}$$
**Inferential Statistics**

- Once we have got our sample
- The key question in statistical inference:
  - Could random chance alone have produced a sample like ours?
- Distinguishing between 2 interpretations of patterns in the data:

**Random Causes:**
- Fluctuations of chance

**Systematic Causes Plus Random Causes:**
- True differences in the population
- Bias in the design of the study
Reasoning of Hypothesis Testing

1. Make a statement (the null hypothesis) about some unknown population parameter.

2. Collect some data.

3. Assuming the null hypothesis is TRUE, what is the probability of obtaining data such as ours? (this is the “p-value”).

4. If this probability is small, then reject the null hypothesis.
HYPOTHESIS TESTING: STEP 1

- State the research question in terms of a statistical hypothesis
  - **Null hypothesis** (the hypothesis that is to be tested): abbreviated as $H_0$
    - Straw man: “Nothing interesting is happening”
  - **Alternative hypothesis** (the hypothesis that in some sense contradicts the null hypothesis): abbreviated as $H_a$ or $H_1$
    - What a researcher thinks is happening
    - May be one- or two-sided
HYPOTHESIS TESTING: STEP 1

- Hypotheses are in terms of population parameters

<table>
<thead>
<tr>
<th>One-sided</th>
<th>Two-sided</th>
</tr>
</thead>
<tbody>
<tr>
<td>$H_0: \mu = 110$</td>
<td>$H_0: \mu = 110$</td>
</tr>
<tr>
<td>$H_{1/a}: \mu &lt; 110$ OR $H_{1/a}: \mu &gt; 110$</td>
<td>$H_{1/a}: \mu \neq 110$</td>
</tr>
</tbody>
</table>
Hypothesis Testing: Step 2

- Set decision criterion:
  - Decide what p-value would be “too unlikely”
  - This threshold is called the alpha level.
  - When a sample statistic surpasses this level, the result is said to be significant.
  - Typical **alpha levels** are 0.05 and 0.01.

- Alpha levels (level of significance) = probability of a type I error (the probability of rejecting the null hypothesis even that H0 is true)

- The probability of a type II error is the probability of accepting the null hypothesis given that H₁ is true. The probability of a Type II error is usually denoted by β.
HYPOTHESIS TESTING: STEP 3

- Setting the rejection region:
  - The range of sample mean values that are “likely” if $H_0$ is true.
  - If your sample mean is in this region, retain the null hypothesis.

  - The range of sample mean values that are “unlikely” if $H_0$ is true.
  - If your sample mean is in this region, reject the null hypothesis.
HYPOTHESIS TESTING: STEP 3

Normal distribution

Fail to reject $H_0$

Reject $H_0$

$Z_{crit}$

$\mu_{H_0}$

$Z_{crit}$

©2016 - Sorana D. BOLBOACĂ
HYPOTHESIS TESTING: STEP 4

- Compute sample statistics

- A test statistic (e.g. Ztest, Ttest, or Ftest) is information we get from the sample that we use to make the decision to reject or keep the null hypothesis.

- A test statistic converts the original measurement (e.g. a sample mean) into units of the null distribution (e.g. a z-score), so that we can look up probabilities in a table.
**HYPOTHESIS TESTING: STEP 4**

- **If we want to know where our sample mean lies in the null distribution**, we convert X-bar to our test statistic $Z_{\text{test}}$.
- **If an observed sample mean were lower than** $z=-1.65$ **then it would be in a critical region where it was more extreme than** 95% **of all sample means that might be drawn from that population.**
HYPOTHESIS TESTING: STEP 5

State the test conclusion:

- If our sample mean turns out to be extremely unlikely under the null distribution, maybe we should revise our notion of $\mu_{H0}$

- We never really “accept” the null hypothesis. We either reject it, or fail to reject it.
**Steps in Hypothesis Testing**

Step 1: State hypothesis ($H_0$ and $H_1/H_a$)

Step 2: Choose the level of significance ($\alpha = 5\%$)

Step 3: Setting the rejection region

Step 4: Compute test statistic ($Z_{test}$) and get a p-value

Step 5: Make a decision
One- vs. Two-Tailed Tests

- In theory, should use one-tailed when
  1. Change in opposite direction would be meaningless
  2. Change in opposite direction would be uninteresting
  3. No rival theory predicts change in opposite direction

- By convention/default in the social sciences, two-tailed is standard

- Why? Because it is a more stringent criterion (as we will see). A more conservative test.
ONE- vs. TWO-TAILED TESTS

- $H_a$ is that $m$ is *either* greater or less than $\mu$
  - $H_a: \quad m \neq \mu$

- $\alpha$ is divided equally between the two tails of the critical region
Two-Tailed Hypothesis Testing

$H_0: \mu = 100$

$H_1: \mu \neq 100$  \text{Values that differ significantly from 100}
One tailed

Reject $H_0$  
Fail to reject $H_0$

Values that differ “significantly” from 100

Values that are significantly less than 100

Two tailed

Reject $H_0$  
Fail to reject $H_0$  
Reject $H_0$

Values that differ significantly from 100

$Z_{crit}$

$0.05$

$0.025$
Testing the Distribution Shape of Continuous Data

- Test of Normality of a Distribution
- Test of Equality of Two Distributions
TEST OF NORMALITY OF A DISTRIBUTION

Why to test the normality?

- The robustness of most tests allows the test to be used if the underlying data are approximately normal
- Test that required a normal distribution assumption:
  - Student t test
  - Z test
  - Tests of analysis of variances
NORMALITY TESTS

- Chi-Square goodness-of-fit: 1900
  - Conservative

- Kolmogorov-Smirnov (KS): 1933
  - Conservative

- Shapiro-Wilk: 1965
## Normality Tests

<table>
<thead>
<tr>
<th></th>
<th>Prefer less conservative test</th>
<th>Prefer more conservative test</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Small sample</strong></td>
<td><strong>Shapiro-Wilk</strong></td>
<td><strong>Kolmogorov-Smirnov</strong></td>
</tr>
<tr>
<td>(5-50)</td>
<td></td>
<td><em>(one-sample form)</em></td>
</tr>
<tr>
<td><strong>Medium to large sample</strong></td>
<td><strong>Shapiro-Wilk</strong></td>
<td><strong>Chi-Square Goodness-of-Fit</strong></td>
</tr>
<tr>
<td>(&gt; 50)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
SHAPIRO-WILK

- Seek a statistical software to use the Shapiro-Wilk test
- Limitation:
  - Some software packages allow only the sample parameters (means and standard deviation) to be used for the theoretical normal against which the data are being tested
Is the sample normal in shape without any a priori mean and standard deviation specified?
- $H_0$: The form of the distribution is normal
- Used the sample’s mean and standard deviation

Did the sample arise from a particular normal distribution with a postulated mean and standard deviation?
- $H_0$: The distribution form which the sample was drawn is not different from a specified normal
The critical values for different significance levels:

- $\alpha = 0.01$: $(1.63/\sqrt{n})-(1/3.5 \cdot n)$
- $\alpha = 0.05$: $(1.36/\sqrt{n})-(1/4.5 \cdot n)$
- $\alpha = 0.10$: $(1.22/\sqrt{n})-(1/5.5 \cdot n)$

1. Arrange the $n$ sample values in ascending order
2. Let $x$ denote the sample value each time it changes:
   - If sample values are 1, 1, 2, 2, 3
     - First $x = 2$
     - Second $x = 3$
3. Let $k$ denote the number of sample members less than $x$
   - If sample values are 1, 1, 2, 2, 3, $x = 2$ and $k = 2$ (we have 2 values less than $x$)
4. Let $F_n(x)$ denote $k/n$ for each $x$
   - = the sample cumulative frequency sum
5. The expected cumulative sum against which to test the sample
   - Calculated for each $x$
   - $z = (x - m)/s$
6. For each \( z \) value, find the expected \( Fe(x) \) as the area under the normal distribution to the left to \( z \)

7. Calculate the absolute values of the difference between the F’s \( | F_n(x) - F_e(n) | \)

8. Test statistic is the largest of these differences, say \( L \).

9. If \( L \) exceeds the critical values, reject \( H_0 \); otherwise, do not reject \( H_0 \).
Example:

- Do the ages of the 10 patients form a normal distribution?
- $n = 10$
- $\alpha = 0.05$
- Critical value: $(1.36/\sqrt{10})-(1/4.5\cdot10) = 0.408$
### KOLMOGOROV-SMIRNOV: ONE SAMPLE FORM

| Age | x  | k | $F_n(x)$ | z           | $F_e(x)$ | $|F_n(x)-F_e(x)|$ |
|-----|----|---|----------|-------------|----------|-----------------|
| 54  | 54 |   | 0.0       |             | 0.0      | 0.0             |
| 61  | 61 | 1 | 0.1       | (61-65.1)/7=-0.586 | 0.279    | 0.179           |
| 61  | 61 |   | 0.0       |             | 0.0      | 0.0             |
| 61  | 61 |   | 0.0       |             | 0.0      | 0.0             |
| 62  | 62 | 4 | 0.4       | (62-65.1)/7=-0.443 | 0.329    | 0.071           |
| 62  | 62 |   | 0.0       |             | 0.0      | 0.0             |
| 68  | 68 | 6 | 0.6       | (68-65.1)/7=0.414 | 0.661    | 0.061           |
| 73  | 73 | 7 | 0.7       | (73-65.1)/7=1.129 | 0.871    | 0.171           |
| 74  | 74 | 8 | 0.8       | (74-65.1)/7=1.271 | 0.898    | 0.098           |
| 75  | 75 | 9 | 0.9       | (75-65.1)/7=1.414 | 0.921    | 0.021           |

$m = (54+61+61+61+62+62+68+73+74+75)/10 = 651/10 = 65.1; s = 7$
$L = 0.171$

$1.171 \leq 0.408 \rightarrow$ Do not reject $H_0$: The distribution from which the sample was drawn has not been shown to be different from normal.
Chi-Squared Goodness-of-Fit

- $H_0$: the distribution from which the sample was drawn is normal (alternatively is normal with parameters $\mu$ and $\sigma$)
- $H_1$: the distribution is different.
- If calculated $\chi^2$ is greater than critical $\chi^2$, reject $H_0$; otherwise, accept $H_0$

\[ \chi^2 = \sum \frac{(n_i - e_i)^2}{e_i} = \sum \frac{n_i^2}{e_i} \]

INTERPRETATION OF NORMALITY TESTS USING P-VALUE

- If the p-value is less than the chosen alpha level, then the null hypothesis is rejected
  - One concludes the data are not from a normally distributed population

- If the p-value is greater than the chosen alpha level, then one does not reject the null hypothesis that the data came from a normally distributed population.

a. Test distribution is Normal.
b. Calculated from data.
Testing Normality!

- The normal shape must be tested in order to be able to applied a series of statistical test
- Normality test could be performed by using statistical software
- It is necessary to know how to interpret a test (critical values vs p-value)
Thank you!

If you torture the data long enough, they will confess.

EUREKA!
